Not illustrated. 1908 Excerpt: .would continue until a slope had been permanently secured, beyond which the added deflexions caused by ordinary loading would not cause stresses above the elastic limit of either the steel or the concrete. But in order to attain this state of affairs, the stress conditions in the beam may have far exceeded safe limits, and many observations have shown this to have actually happened in more than one building. The dangers incident to such tension cracks adjacent to points of support are numerous. They occur where the shear in the beam is a maximum and unless ample reinforcement is introduced to resist these latter stresses (as is really very rarely done), their unit values will run up far beyond limits usually considered safe. These initial tension cracks also serve as starters for others which tend to occur from the diagonal principal tensile stresses. Cracks of the latter variety are apt to develop suddenly, producing destructive failure in (test specimens, and there is no reason to suppose that more immunity would be found to inhere in actual structures, should the load ever reach a critical value. With the formation of such cracks, the zone of compression is obviously restricted to the uncracked part of the concrete, and if the crack is driven across the initial position of the neutral axis, the unit stresses in the extreme concrete layer must exceed permissible, safe ones. Then, too, in the cracked condition, the concrete can have no tensile value, and...
